

# Computational Tools and Resources for CRISPR/Cas 9 Genome Editing Method

## Abstract

CRISPR/Cas9, the popular genome editing method, has wide applications ranging from genetic engineering of plants, modifying bacterial genomes for production of therapeutic, agricultural, industrial bioproducts. It would be an understatement to claim that it has indeed revolutionized the field of gene and genome editing. To aid the researchers in designing the optimal sequences for CRISPR/Cas9 experiments, a multitude of bioinformatics tools and resources have been developed and are currently used. This review aims to provide an up to date list of tools, web servers, databases, and other resources that can be used for editing the genome. We hope that such a compilation will enable researchers to select the resources based on functionality, ease of use, availability, and specific research needs.

**Keywords:** CRISPR/Cas9; Genome editing; Bioinformatics; Resources; Database; Computational tools

## Mini Review

**Abbreviations:** CRISPR-Cas9: Clustered Regularly Inter-Spaced Palindromic Repeats-CRISPR associated proteins 9; crRNA: CRISPR RNA; DSB: DNA Double Helix Break; sgRNA: Single Guide RNA; TALENs: Transcription Activator-Like Effectors Nucleases; tracrRNA: Transactivating CRISPR RNA; ZFNs: Zinc Finger Nucleases

## Introduction

From an evolutionary point of view, archaea and bacteria have evolved to survive and blossom as communities in active environments that are, in general, stressful and unpredictable. Specifically, the abundance of viruses attacking microorganisms is a constant threat; in addition, the mutation and recombination rates in viruses make them fast-evolving predators. To sustain against such predators, archaea and bacteria have evolved to have a new multilayered defense system that has been identified as CRISPR/Cas9 [1]. Consequently, many labs have tapped into the potential uses for this method and active research to unravel the mechanism has paved a unique path in the development of targeted genome editing techniques [2]. Among the various genome editing methods, TALENs, ZFNs, and CRISPR-Cas9 are the three foremost methods [3].

The advantage of CRISPR as a more reliable method is the ease in the creation of a break in the helical strand using RNA-guided nucleases that involve canonical base pairing between the target DNA region and the RNA designed for binding to it. These inducible alterations in the genome provide a potential avenue for not only transferring traits in livestock and crops, but also to rectify diseased genes for human therapeutics with application in gene therapy. Another advantage is the non-dependency on protein-based system such as ZFNs and TALENs [4].

CRISPR-Cas9 system is made of three components, viz: a small non-coding RNA called tracrRNA, a 20 nucleotide containing RNA sequence called crRNA that binds to the target DNA, and a RNA sequence repeat of 19-22 bases; and a Cas protein encoding operon. For simplification of the system for targeted mutations, a sgRNA with unique restriction sites for specific insertion of the target by combining endogenous tracrRNA and crRNA [5].

CRISPR-Cas9 gene editing technology can generate transformative medicines in health sector such as the production of antimicrobials, animal health and therapeutic bio products. In the case of agricultural biotechnology, the CRISPR-Cas9 technology aids in unraveling of both functional and phenotypical data about target plants and enhancing their resilience against drought and disease [6]. CRISPR-Cas9 technology is a valuable tool in biological research specifically to modify genes through knockout studies, inserting specific sequences, up-regulation and down-regulation of genes. The profound use of CRISPR-Cas9 technology has acknowledged by several researchers in generating accurate and efficient models of disease in cell lines, primary cells, and animal models [7]. CRISPR-Cas9 technology provides a precise method to improve industrially important microbial strains as cell factories (Eg: fermentation) for production of food, pharmaceutical, and biofuel products [8].

CRISPR's extensive applicability via gene editing and its easy rules for designing sgRNA has provided an excellent opportunity for bioinformatics researchers to get an insight of various aspects of CRISPR mechanism using computational approach and development of software that identifies potential sgRNA sequences in genomes. Although, several design tools, web servers, and databases exist not all of them are similar. Specifically, each has an advantage over the other. Hence, to make the job easier for

researchers around the globe, there is a need to keep an eye for various CRISPR design software based on some of the potential advantages, such as functionality, ease to use, its availability and more specifically research needs.

## Software and web servers for designing sgRNA sequences

Table 1 lists the currently available software (standalone and web server) that are used for designing sgRNA for CRISPR/Cas9 experiments. While previous reports have listed the available software/web server for CRISPR/Cas9 experiments, some of the resources are inaccessible, for unknown reasons. For example, the web servers ZiFiT, Cas9-Design, Jack Lin's CRISPR/Cas9 gRNA

finder, and GT-Scan are no longer accessible. Among the 54 web servers listed in Table 1, more than 20 resources are available for public use since 2015, in comparison 13 webservers have been reported in 2016, and most recently one web server (CRISPR-RT) has been published in 2017.

Additionally, there are 5 software that can be used in the standalone mode, by either running a Perl script (sgRNACas9) or via using an R code (caRpools) (Table 2). There are also desktop based applications (DESKGEN) that can be utilized by molecular biologists for designing sgRNA sequences. The potential drawback to the standalone versions could be software compatibility, ease of usage, and additionally, some may be available for a fee.

**Table 1:** List of software and web servers for designing sgRNA sequences.

### Databases for designing CRISPR/Cas9 genome editing

Almost all of the tools listed in Table 1 most likely have an

inbuilt database for designing sgRNA sequences. However, for the sake of simplicity, we have listed 5 resources as "databases", which have collated the sgRNA sequences and they can be easily accessed. We have included COSMID in both web server and database as it is an advanced resource available for users [74].

### Discussion

Microbes are the cell factories for the production of therapeutic and industrial biological products. Until recently, metabolic engineering is at the forefront as a paradigm changing research area by which genomes can be edited as desired. Nowadays, CRISPR and its associated proteins (Cas) are currently popular for precision genome editing in many organisms. Based on the global market statistics, the genome editing market is expected to touch around USD 5.54 Billion by the end of 2021 with a CAGR of 14.3%. Among the different genome editing technologies, the CRISPR segment stands alone with the largest share of the global genome editing market due to the ease of technology [75].

## Conclusion

In this mini-review, we have highlighted an updated and currently accessible compilation of software (standalone and web server) and databases that are used for CRISPR/Cas9 genome editing method. With the availability of multiple resources for sgRNA design, the prediction accuracy and validated benchmark sets are utmost important for efficient targeted genome editing research.
